Dashboard Block Descriptions

Before building the dashboard, I wrote down all the questions the team asks every month and grouped them by type: "what's happening now," "why," and "what to do next." Each group got its own block. The goal was for someone to open the dashboard and understand the full picture within 2 minutes — no follow-up questions needed.

KPI Tiles — "What's happening now?"

The top row of the dashboard shows eight numbers that give an instant snapshot: Total Spend, Revenue 7d, Revenue 90d, ROAS 7d, ROAS 90d, New Users, Payers, and Conversion Rate. I deliberately included both revenue horizons — 7d and 90d — because they tell different stories. ROAS 7d shows immediate return, while ROAS 90d reflects true user value, given that most users don't pay right away. All tiles respond to the date filter, so to view a specific month you simply set the desired range.

Revenue Period Toggle (7d / 90d)

I added a parameter toggle on the right side of the dashboard that dynamically switches the ROAS horizon across all charts except the KPI tiles. This makes it easy to compare short-term return with long-term payback without changing the layout — useful for checking whether a channel with low ROAS 7d recovers at 90d.

Revenue vs Spend — "Is the business breaking even overall?"

A combined chart: bars show monthly spend, the line shows revenue. It lets you see at a glance whether revenue is catching up to costs, where the gaps are, and how the balance shifts month over month. I chose the bar+line combination because two sets of bars would have lost the revenue trend, while two lines would have lost the scale of spend.

ROAS by Channel — "Who's profitable?"

A horizontal bar chart with a dashed reference line at 1.0 — the break-even point. If a bar doesn't reach the line, the channel is unprofitable. I chose the horizontal format because channel names read naturally from left to right, and the eye moves intuitively from the channel to its result. Color encodes the channel, and comparison against the break-even line makes the verdict readable at a glance. Answers the question: "which channel is the best and worst this month?"

ROAS Trend — "How has performance changed?"

A line chart with a separate line for each channel over time. The trend gives important context: you see not just the delta but whether a drop is a one-off or a systemic shift. The sharp decline in recent months is a data artifact, not a real performance issue (details in the Assumptions section).

Geo Heatmap — "Where does what work?"

A matrix of geo × channel where each cell is colored by ROAS — from light blue (low ROAS) to dark blue (high). I chose a heatmap over separate charts per geo because it surfaces patterns at a glance: for example, Email is dark blue everywhere, while TikTok is light across every market without exception. That immediately answers the question "maybe TikTok is just poorly set up in one country?" — no, the problem is systemic.

Budget Quadrant — "Where to scale, where to cut?"

A scatter plot with spend on the X-axis, ROAS on the Y-axis, dot size by number of new users, and color by channel. Two reference lines — average spend (vertical) and ROAS = 1.0 (horizontal) — divide the space into four zones, each with a clear action. This is the central block for budget decisions: it answers two questions at once — efficiency and scale. I picked a scatter plot over a table because it reveals distribution and outliers — for example, Email sitting alone in the upper-left corner, far ahead of everything else.

Channel Spend % — "Where does the money go?"

A treemap where each rectangle's area represents the channel's share of total spend. I chose a treemap over a bar chart because it shows proportions immediately: Meta and TikTok together account for ~71% of the budget — and both channels are unprofitable. This is the strongest argument for reallocation: 71% of the money is going into the worst-performing channels.

Device OS — "Does the device matter?"

Two side-by-side bar charts: conversion to payer and average revenue per user across iOS, Android, and Web. I separated this into its own block because the question "should we redistribute budget by device?" is a distinct hypothesis that deserves its own answer. The data shows Android converts better, but iOS users pay more — a critical nuance that gets lost if you only look at conversion rate.

Budget Recommendations for Next Month

Data covers the full period. Total Spend: \$2,223,295. Break-even threshold: ROAS = 1.0. Company-wide average ROAS (90d): 0.48x. All ROAS figures below are for the 90d horizon.

Channel	Action	Change	Rationale
Email	Increase	+30%	ROAS 2.44x — the only channel above break-even, 5x higher than the company average (0.48x). At the same time, spend is the lowest of all channels (~\$98K, just 4.4% of the budget), which suggests under-investment. We're scaling cautiously at +30% — this is the upper limit the existing subscriber base can support. If ROAS holds after the increase, the next step is to expand the base via lead generation
Google	Hold	0%	ROAS 0.88x — the closest to break-even after Email. Spend ~\$544K (24.5% of the budget). The Geo Heatmap reveals a sharply asymmetric pattern: ROAS 1.24 in the UK and US (above break-even), but it drops to 0.33-0.59 in continental Europe (DE, PL, UA). This is unusual for a global channel and looks more like a localization issue (creatives, landing page language, audience relevance) than a problem with Google itself. Before cutting the overall Google budget, it's worth testing localization hypotheses for DE/PL/UA
Meta	Decrease	-30%	ROAS 0.35x — three times below break-even. Spend is significant (~\$823K, 37% of the total budget). The ROAS Trend chart shows that Meta held steady at 0.4-0.45 for most of the year, but starting in October 2025 ROAS dropped to 0.2-0.25 and never recovered. This isn't a seasonal anomaly — it's a structural break in the trend,

Channel	Action	Change	Rationale
			suggesting possible audience fatigue or post-Q4 algorithm changes on Meta's side. Worth investigating what changed during that period. Shutting Meta down entirely isn't advisable — the channel may still deliver users with long-term LTV
TikTok	Decrease	-70%	ROAS 0.08x — effectively zero return across every geo without exception. Heavy spend (~\$759K, 34.1% of the budget) producing minimal revenue. We're keeping a minimum budget only to preserve the account and leave the option to revisit the test later
Device OS	Prioritize iOS	—	iOS users generate 1.4x more revenue per user (\$2.62 vs \$1.87 on Android) — more than enough to offset iOS's lower conversion rate. Once spend data becomes available at the device_os level, I recommend reallocating budget toward iOS traffic

Assumptions

1. Sharp ROAS decline in recent months

All channels show a steep ROAS drop in the most recent months on the Trend chart. This is almost certainly a data artifact rather than real underperformance — revenue_90d hasn't yet accumulated for users registered in the last 3 months at the time of extraction. In other words, the spend is already counted, but the revenue isn't. This should be factored in when reading trends for the last quarter.

2. ROAS = 1.0 as the break-even threshold

We used this as the baseline — \$1 spent returns \$1 in revenue. In reality, the target ROAS may be higher if there are operating costs to cover, or if the company optimizes for LTV rather than short-term payback. If the company's target ROAS is different, the reference lines and recommendations need to be recalculated.

3. Device OS and budget allocation

Android shows a higher conversion rate (18.47%) than iOS (16.03%) and Web (13.79%), but iOS produces higher revenue per user (\$2.62 vs \$1.87). This means iOS users pay less often but spend more. A full budget reallocation by device would require spend data broken down by device_os — which isn't available in the current dataset. Spend is recorded at the channel × geo level and not broken out by OS.

4. Email as a channel

Email shows an unusually high ROAS (2.44x) with very low spend (~4.4% of the budget). Possible explanations: the channel is naturally cheaper (no auction dynamics like in paid channels), the data is incomplete, or it's actually a retention channel for the existing base rather than an acquisition channel. The +30% recommendation is intentionally cautious to account for this uncertainty and the natural ceiling of the existing subscriber base.

5. TikTok — lots of users, little revenue

On the scatter plot, TikTok has the largest dots in terms of new users — meaning the channel acquires traffic cheaply and at high volume. But ROAS 0.08x indicates that these users barely pay. This could mean TikTok's audience doesn't match the product's paying-user profile, or that creatives are attracting the wrong audience. The recommendation to cut 70% takes this into account — fully shutting down the channel isn't advisable until the creative-quality hypothesis is tested.
